Descriptive Report

To accompany topographic sheet entitled

Treasury Department

U. S. Coast and Geodetic Survey

O. H. Hettmann, Superintendent

Topography of

Port Etches

Prince William Sound

Alaska

Executed by H. G. Appleton, Chief Office

James M. Achree

F. Westdal, Assistant, Commanding

1902

Scale 1:20,000

This projection was sent from the Office and was originally intended for the topographic survey of the shore from Johnstone Point to and including Port Etches, but for reasons stated in the descriptive report of the northern sheet of the entrance another projection on scale 1:10,000 was made on board for that purpose. By changing the minutes of longitude a considerable distance to the eastward it was found
that it would do for the topographic survey of Port
Etches. At the request of Mr. W. T. Appletorn
for an opportunity to gain some experience in plane-
table work, I instructed him in the use of the instru-
ment and started work on the sheet when a sufficient
number of triangulation points had been computed
and plotted upon it. When Mr. Christian finished
the northern distance sheet, the party in the charted
scheme was turned over to Mr. Appletorn for the
topographic and hydrographic survey of Port Etches,
and this is the result of the former. On account of
the scarcity of weather fit for topographic work,
contouring was not attempted. Therefore, the summits
of the peaks and ridges could be seen; they were cut
in and heights approximately determined, but they
were not all seen, particularly in the region back of
English Bay and eastward from it.

The general topographic features of Port Etches
resemble those already described in the reports of
other sheets. I have there called attention to the
two main ridges forming Kinchinbrook Island and
that Port Etches lies in the depression between them
at their southwestern ends. This is true when consider-
ing the larger topographic features of the entire

and the Southern main: ridges of Hitchinbrook: Id: Il.
island and its relations to ridges on adjoining islands and the mainland. When describing Fort Etches in particular it is necessary to state that there is a third ridge, not so high nor so long as the two already mentioned, and evidently a branch from the northern main ridge as the lowest divide between the two main ridges lies to the southward of this subordinate third ridge. The depression between it and the northern ridge forms the lagoon called Constantine Harbor, a comparatively shallow sheet of water the natural outlet of which has become closed by a very remarkable ridge of shingle and boulders, probably the terminal moraine of the glacier which caused the lagoon originally, since reinforced by wave action in grinding up the material of which it is composed and carrying the lighter parts upward. The waters of the lagoon have forced another outlet at a point about two miles from the present extremity of this subordinate ridge where a low place probably existed in it originally, and which has since been worn deeper by the strong in- and out-flow of the tidal waters of this shallow basin. The detached portion of this ridge is about three hundred feet high near its northeastern end and falls rapidly into a lower terrace of about fifty feet elevation above the
Bear Cape and Northern Ridge, showing the steep southern slope.

sea, like the fragments of it found elsewhere around
the shores of Hinchinbrook and Montague Islands. The
Porpoise Rocks are evidently remains of it as the prin-
cipal islands are flat on top and of the same general level
above the sea, and the reef connecting them with the
extremity of the ridge points to a former, now receded,
expanding connection between them. To the northward
of the mouth of Constantine Harbor the subordinated
ridge rises rapidly to heights of twelve hundred and
eighteen hundred feet, then decreases to seventeen hundred
and fifteen hundred feet; whereas the northern
and southern main ridges on either side reach eleva-
tions of twenty-three hundred and eighty and twenty-
two hundred and sixty feet respectively. The striking
peculiarity about all of them is the gradual slope on
the north sides and the more abrupt descents on the
south, as witness the northern main ridge from Bear
Cape all along the northern shore of Constantine Harbor,
the steep southern slopes of the subordinated ridge toward
Port Etches, and the southern main ridge towards the
sea along the southeast coast of Hinchinbrook Island,
described elsewhere. The timberline reaches an eleva-
tion of about one thousand feet, above which occurs
scattered scrub trees and thick brush.
Constantine Harbor has four islands within it, one of which lies almost in the center of the shingly ridge above described and therefore strictly not now an island. Their foundations are rock with strata almost perpendicular and not higher than about twenty to thirty feet above high water, and all covered with scrub timber and brush. Down the steep slopes of the ridge on the north side of the lagoon pour several streams of pure water. Their streams issue from the mountain side above the timber line and are undoubtedly fed by the many lakes and remains of glaciers upon the broader summit of the ridge, and find their way through and under the loose, volcanic debris above the timber line and brush. Sometimes these Constantine Harbor to fill water from these streams, and the inhabitants of the village of Kuchra bring their drinking water from them. Pure water is seen on the peninsula which divides this lagoon from Port Etches thus bring only a lake of brown swamp-water unfit for use immediately south of the village. Rain is however almost incessant and so copious that water pours over the edges of the cliffs in every depression.

Harbor lie three small rock-islets of peculiar shape, more particularly described in the report of the hydrography of Port Etches, which probably are remains of the low terrace which bordered the subordinate ridge. There are several other smaller and lower rocks close to the beach northeastward from the three prominent ones which exhibit the same characteristics as to topography.

Along the southeast shore of Port Etches are four indentations in the otherwise almost straight line of coast, and the points on either side of these lights are fragments of the low, bordering terrace, ending in cliffs about fifty feet high. Back of each of these indentations is low land containing lagoons and lakes, gradually rising into wide semicircular valleys, tracking far in towards the high ridge. High up under the rims of these valleys can still be seen the remains of the glaciers which carved them into shape and pushed their restless way through the bordering table land to join the large body of ice which filled Port Etches. The northeast point of the indentation which has been named Mosquito Light is an exception to this general rule in that it rises rather abruptly into a conical, star-covered...

hill about eleven hundred feet above the sea and connected with the southern ridge by a much lower neck. The remains of the table land even here are not totally obliterated, in that the islands, one immediately off the point and another about twenty feet high on its prolongation, with some rocks between them, almost covered at high water, testify to its former existence.

The Porpoise Rocks, included on this sheet, are about forty to fifty feet high, like the table land and bordering cliffs of the point with which they have probably been connected. These are three principal islets, with numerous small rocks between and around them. The westernmost of these, upon which the triangulation station “Porpoise” is located on the southern extremity, is the largest and has a luxuriant crop of grass on its flat summit during the summer season. There is no sign of any large growth, and probably no bushes or trees would flourish there owing to the tremendous force of the illi-waves which sweep over it. Even during the summer months these are very violent. The signal erected by the party on its summit was swept off the islet twice during July and August although but twenty
first high and consisting only of centerpoles and three braces with some muslin banners tacked to the pole. The third signal erected, there was reduced to ten feet in height and secured by braces to a platform upon which several packs of sand were piled up. This remained in place when the ship sailed. The other isles have no soil upon them and are not so flat on top. All of them exhibit the same peculiarity as the rock-isles off the mouth of Constantine Harbor in that the bases are worn by wave and action so that the summits overhang, and they cannot be readily scaled without the help of ladders.

Kekitch village is situated at the southern extremity of the Shingle ridge which divides the waters of Constantine Harbor and the Sound, thus enabling the inhabitants to launch their kayaks in either of them. It is a very old settlement of natives, at present a mixture of Eskimos and Aleuts, and numbering probably about one hundred souls. There are from twenty to thirty houses in all, mostly built of boards and painted in the white man’s fashion, but there are many original native kuts among them. The place has been of much greater importance formerly and was occupied as a trading station by the old...
Russian American Fur-trading Company, since very early days. Some of their more ancient built of large logs still stand though much decayed. Their successor, the Alaska Commercial Company, maintained this trading post until recent years but have now abandoned it.

Their last Agent, a white man married to a half-breed Russian woman, still resides here and carries on some trade on his own account. He and the priest in charge of the Russian Greek-Catholic Church located here are the only white residents of any permanent character. The natives eke out a precarious existence by fishing, hunting the almost exterminated sea-otter, bear, and other fur-bearing animals, and some of them work in the canneries at Ocina and Dyak during the busy season.

For further information regarding Port Alice I beg to refer to the descriptive report of the hydrographic chart of this locality.

Respectfully submitted,

Ferdinand Mettetal
